

Workshop::Cluster Extension & GitLab Repository

Luca Morandini

Head of AI Engineering – Melbourne eResearch Group

University of Melbourne

luca.morandini@unimelb.edu.au

Replace a Failing Node

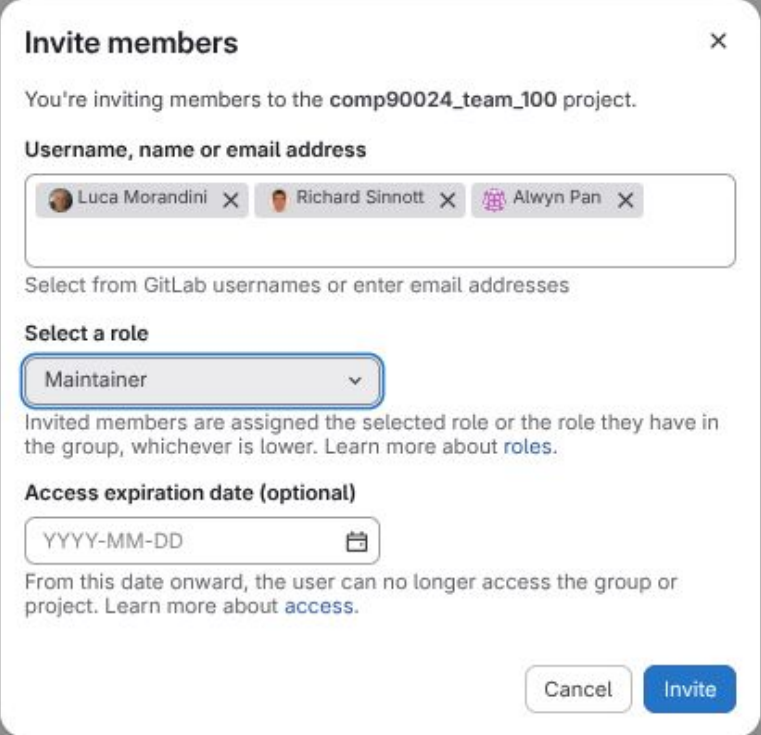

- Let's add a default worker (provided the cluster has 3 worker nodes):
`openstack coe cluster resize --nodegroup default-worker comp90024 4`
- Check the node creation with `kubectl get nodes`
- Cordon the failing node: `kubectl cordon <node name>`
- Drain the failing node from: `kubectl drain <node name>`
- Find the node ID: `openstack server list | grep <node name>`
- Remove the failing node: `openstack coe cluster resize --nodes-to-remove <failing node id> --nodegroup default-worker comp90024 3`
- Check the nodes with `kubectl get nodes`

Create the Repository

- One team member (and only one member) has to create the repository using his/her GitLab personal repo
- Create a private blank project with the README file and use the name `comp90024_team_<team#>`
- Use the GitLab user interface to create the following directories:
 - frontend
 - backend
 - test
 - database
 - data
 - docs
 - llm

Configure the Repository

- Invite your team members as maintainers (the action is available under manage/members)
- Invite, as maintainers, the teaching staff
- Copy the repository SSH address (under code/clone with SSH)
- Open a shell and clone the repo using `git clone <ssh address>`
- The repository should have been copied under the directory `comp90024_team_<team#>`

Invite members ×

You're inviting members to the `comp90024_team_100` project.

Username, name or email address

 Luca Morandini ×  Richard Sinnott ×  Alwyn Pan ×
